Problem formulation

Example: Predicting movie ratings

→ User rates movies using ~~one~~ to five stars
 zero

Movie	Alice (1)	Bob (2)	Carol (3)	Dave (4)
Love at last	5	5	0	0
Romance forever	5	?	?	0
Cute puppies of love	?	5	0	?
Nonstop car chases	0	0	5	4
Swords vs. karate	0	0	5	?

$$n_u = 4$$

$$n_m = 5$$

Purpose: try to predict the rating number

→ n_u = no. users

→ n_m = no. movies

→ $r(i, j) = 1$ if user j has rated movie i

→ $y^{(i, j)}$ = rating given by user j to movie i (defined only if $r(i, j) = 1$)

→ For each user j , learn a parameter $\theta^{(j)} \in \mathbb{R}^3$. Predict user j as rating movie i with $(\theta^{(j)})^T x^{(i)}$ stars.

$$x^{(3)} = \begin{bmatrix} 1 \\ 0.99 \\ 0 \end{bmatrix} \leftrightarrow \theta^{(1)} = \begin{bmatrix} 0 \\ 5 \\ 0 \end{bmatrix}$$

Result of the prediction

Problem formulation

- $r(i, j) = 1$ if user j has rated movie i (0 otherwise)
- $y^{(i, j)}$ = rating by user j on movie i (if defined)

→ $\theta^{(j)}$ = parameter vector for user j

→ $x^{(i)}$ = feature vector for movie i

→ For user j , movie i , predicted rating: $(\theta^{(j)})^T (x^{(i)})$

→ $m^{(j)}$ = no. of movies rated by user j

To learn $\theta^{(j)}$:

3. You run a movie empire, and want to build a movie recommendation system based on collaborative filtering. There were three popular review websites (which we'll call A, B and C) which users go to rate movies, and you have just acquired all three companies that run these websites. You'd like to merge the three companies' datasets together to build a single/unified system. On website A, users rank a movie as having 1 through 5 stars. On website B, users rank on a scale of 1 - 10, and decimal values (e.g., 7.5) are allowed. On website C, the ratings are from 1 to 100. You also have enough information to identify users/movies on one website with users/movies on a different website. Which of the following statements is true?
